The New KFI

KFI is now in the super-power class, having recently increased power to 50 kilowatts—the first station west of Texas to use this power. This article provides a detailed description of the new transmitter.

By I. R. Baker

(a) Low-power rectifiers and control panel
(b) Exciter modulator unit
(c) 5 kw. amplifier
(d) 50 kw. amplifier
(e) Main control panel
(f) Main rectifier
(g) Basement apparatus
(h) Antenna tuning equipment

One of the illustrations shows the entire radio-frequency unit. On the extreme left is the low-power rectifier and automatic control unit. This panel contains three individual mercury vapor rectifiers, various contactors and relays associated with the control circuits, and condensers and reactors associated with the oscillator-modulator amplifier panel. There are a total of ten UX-896's in this panel which supply power to the various radio-frequency stages located in the first three panels.

The Modulator Unit

The next panel shown in the same illustration is the exciter modulator unit. This panel performs the following functions: (1) produces a constant frequency by means of a crystal control oscillator, (2) amplifies the carrier frequency to a power level to excite the succeeding 5 kw. amplifier, and (3) receives low-level audio energy from the incoming audio line and amplifies this to the level sufficient to modulate the radio-frequency system 100%.

The two complete crystal oscillator units are mounted side by side in this unit behind glass-front doors. The connections are so arranged that either of the crystal units can be used at will, depending upon the position of the crystal unit transfer switch.

The crystal oscillator stage employs one UX-210 tube, connected in the circuit with a quartz crystal accurately ground.

The R.F. Portion of the Transmitter Equipment

The three panels at the left contain, respectively, the low-voltage rectifier and automatic controls, the exciter and modulator equipment, and the 5-kw. intermediate amplifier. To the right of the gate are two of the panels on which the 50-kw. amplifier equipment is mounted.
to a frequency of 640 kc. at a specified temperature. In order to insure the highest degree of frequency stability, the crystal is mounted in a specially designed holder and is kept in place by quartz spacers. These spacers are ground from the same block as the crystal and therefore have the same temperature coefficient, thus keeping the air gap constant with changes in temperature. The crystal holder is mounted inside a specially designed heated compartment with thermostatic control so that the constant temperature is maintained at the crystal. The heater unit is known as an attenuated heater.

**Crystal Temperature Control**

A sensitive thermostat is located in the vicinity of the source of heat so that it operates on a very small temperature change of the heater element itself. Due to the great thermal capacity of the conducting layer, the resultant change in temperature around the crystal is but a small fraction of the change in temperature which causes the thermostat to operate. In this manner the frequency variations of the temperature changes are kept within very narrow limits. In order to maintain accurate temperature at the crystal itself, a thermometer projects from the oven and accurately indicates any changes which may take place therein.

The power required for the heater is obtained from the 110-volt station lighting circuit instead of from the control circuit used in other parts of the transmitter. Thus the unit can be kept at the proper temperature whether the transmitter or the crystal unit is in regular service or not.

The crystal stage is followed by two buffer amplifier stages, all located in the same cabinet, as stated before, the cabinet is in duplicate, including power supply. The two buffer amplifier stages have identical circuits and use UX-865 screen-grid tubes. The screen-grid feature, of course, eliminates the need of neutralizing. Any reactions from the tuning and buffer amplifier stage are not reflected back to the crystal oscillator. Individual shielding is used to further reduce induction between stages. Each stage has its individual plate current meter; the plate voltage on the amplifier and oscillator is measured by means of a voltmeter.

**THE TRANSMITTER BUILDING**

Houses the new 30-kw transmitter and power supply units.

There is still a third unit in the spare parts kit of the transmitter which can be pressed into service in the event one of these two units in the transmitter should be removed, thus always giving a large factor of safety in operation.

Referring again to the block diagram, Figure 1, it will be noted that following the crystal control units is the first r.f. amplifier, which utilizes another screen-grid tube, type UX-660, of 75 watts capacity. This is the third buffer amplifier stage between the crystal and modulated stage. It can be readily seen that so many stages are not necessary for providing the necessary power to excite the modulated stage. It is generally conceded, however, to be good engineering practice to have as many buffer amplifier stages as economics will permit between the modulated stage and the crystal stage to prevent any reaction which might occur due (Continued on page 714)
to modulation. It also allows the crystal stage to be operated at very low power output which, in itself, makes for better stability.

Following the UX-860 stage is the modulated amplifier consisting of one UV-849 tube. This stage is modulated by two of the same type tubes. The power for this stage and the driving stage is furnished by six UX-866 tubes located in the first panel from the left and arranged in a three-phase, full-wave circuit.

The output of this stage is a modulated radio-frequency with peak power of approximately 800 watts delivered to the grids of the succeeding 5 kw. amplifier stage.

The 5 kw. amplifier stage is the third panel from the left. This stage utilizes two of the UV-863 high-power tubes connected in a push-pull circuit. This stage is operated Class B and is used to amplify the modulated carrier from the preceding stage. The UV-863's utilize water cooling on the plates. Filament power for this stage is secured from a filament motor generator set which is used to supply both this stage and the final power amplifier stage. Plate voltage is secured from the high-power rectifier in the same manner by means of a voltage reducer unit.

The next grouping of panels contains the final power amplifier unit which utilizes two UV-862, 100 kw. Radiotrons arranged in a linear balanced power amplifier circuit.

The 100-kilowatt tube was developed specifically for use in 50-kilowatt transmitters, since it was desirable, in the opinion of engineers, to avoid a paralleling of tubes in Class B operation. The adjustment of a Class B amplifier is very critical and unless extreme care is taken in the design and adjustment of the circuit, the amplifier will be unstable.

This instability manifests itself in poor quality, short tube life, interruptions of service and flashovers. The final power amplifier was virtually designed around the 100-kilowatt tube. A great amount of time and money was spent in the development of the circuit for this tube and this work has resulted in a very stable and highly efficient circuit.

A Class B or linear amplifier, by definition, is one that operates in such a manner that the power output is proportional to the square of the grid voltage. This is accomplished by operating the tube with a grid bias of such value that it substantially cuts off the plate current without excitation. When grid voltage is supplying excitation to the tube, essen-

### THE BASIC DIAGRAMATIC ARRANGEMENT

**Figure 1.** Here the functional divisions of the transmitter are shown in their sequential relationship, from crystal-controlled oscillator to the antenna.

Reliable Short-Wave RECEPTION

To Use with your present Set, attached in 10 minutes NATIONAL NC-5—most powerful converter made.

For Serious Short-Wave work, this outstanding instrument, the NATIONAL SW-5 THRILL-BOX is recommended.

READ WHAT USERS SAY:

"Truly a masterpiece in the SW field." . . .
"No comparison possible with other receivers." . . .
"Works perfectly and surely brings in the DX" . . .
"Have had years of SW experience and I have never seen a receiver that really approaches the NATIONAL SW-5. THRILL-BOX in performance." . . .
"5 continents and 23 countries received." . . .
"They don't make SW Receivers better than the NATIONAL SW-5.

Won't I Ever Get Ahead in Radio?

Progress in radio is determined purely by brainwork, not by brains. Practical experience doesn't help you if you haven't got a full knowledge of radio fundamentals.

There's more to radio than just knowing how to repair or construct equipment. You've got to know why it operates after you do it.

To men who are striving toward real future in radio--whether as Service Men, Factory Engineers, Transmission Men, Operators or Broadcast Engineers--we offer an endorsed course of training that by teaching BASIC RADIO ENGINEERING, makes you fit to hold these important jobs.

Get the Details

The coupon brings your interesting booklet and full particulars by return mail. No obligation. Mail it now--while you think of it.

Capitol Radio Engineering Institute, Inc.

Water temperature indicating thermometers.
Filament no-voltage protection on both d.c. and a.c. tube filaments.
Bias no-voltage relays.
Timed filament voltage build-up.
Step starting for the power rectifier.
Overload relay on circuit breakers for both branches of power circuit.
Power rectifier surge overload relay with automatic reset.
Power rectifier sustained overload trip.
Intermediate rectifier overload trip.
Sequence interlocks that protect each successive operation in either starting or stopping.
Thermal overload relays in each motor starter circuit.
Fuses in all branch circuits.
Disconnect switches in high-voltage circuits.
Filament burn-out relay on the 5-kilowatt amplifier that preserves plate power when circuit unbalance is caused by tube failure; and removes filament voltage where both tubes take their

The output from this rectifier is amplified filtered by means of inductive reactors and banks of high-voltage condensers. The reactor is placed on the negative side of the high-voltage delivery circuit.

The transmitter can be thrown on and off by means of a single switch. This switch is provided in duplicate with one control located on the operator's desk.

The final stage contains a rectifier circuit utilizing a UV-217C for rectifying the r.f. and providing a source of power for the monitoring speaker and the oscillograph. The oscillograph enables accurate check on percentage modulation, distortion and improper adjustments.

The frequency characteristic of the KFI transmitter is substantially flat from 50 to 10,000 cycles. This insures high-quality transmission. A characteristic curve is shown of the frequency plotted against decibels in Figure 5. This curve shows that perfect fidelity is secured as far as the human ear can detect, since the average ear cannot detect a change of less than 2 db.

Peak plate current = 0.6 A

On 3-phase, full-wave connection, the inverse voltage is equal to 1.045 times the average d.c. output.

In the single-phase, full-wave rectifier using two tubes, the inverse peak voltage equals 3.14 times the average d.c. plate voltage.

Panel voltage = 5. Fil. current = 60 a. Maximum peak inverse 20 KV.

The remarks in regard to the 3-phase, full-wave 866 rectifier apply here with equal force.

The primary power source for the KFI transmitter is a 2300-volt, 3-phase, 50-cycle supply. This supply is converted by means of a frequency converter to 60 cycles. By using a converter the installation of a standard 60-cycle transmitter tank was made possible. It is interesting to note that this is the only 50 kw. installation in the United States operating from a 50-cycle power source.

When in regular operation there is approximately 100 kilowatts of power from the tubes which must be dissipated. This power is dissipated by means of a water-circulating system. Since there is a very high voltage on plates of the tubes, it is necessary to use distilled water so the mineral content and conductivity will
be low. A long column of water flowing through a rubber hose on a reel is used to insulate the high voltage from the metal pipes. The cooling system consists, essentially, of the following: A water storage tank, centrifugal water pump, radiator and blower. The water storage tank is provided, since the system is a closed one. The pump, of course, circulates the water and has a capacity of approximately 55 gallons per minute against an 80-foot head. A by-pass system is provided around the pump, with the control valve for pressures conservation.

The pump forces the water through the radiator, where the water is diffused through a bank of radiating fins. The radiator is equipped with a centrifugal blower driven by a totally enclosed 7½-horsepower motor. The radiating system, as a whole, is designed to dissipate a much greater amount of power than is ordinarily required of it.

All power equipment, exclusive of that mentioned, is located on the basement floor. This consists of high-voltage transformers, filament generators, high and motor generators, reactors and condensers and voltage regulator for the high-voltage plate supply.

The voltage rectifier is so designed that when voltage is thrown on the tubes it is only 10,000 volts. The regulator automatically runs the voltage up to the normal voltage of 18,000 volts in a very short time. This gives added protection to the tubes. When the transmitter is thrown off, the voltage regulator drops immediately to 10,000 and the transmitter is ready to go into operation at low-voltage plate voltage. The regulator, of course, can be operated separately and by a raise/lower button.

The rectifier is of three-phase, full-wave system, employing a recently developed low-loss mercury vapor rectifier tube. The resistance of these tubes is low that the 1R drop is only 14 volts. The 1R loss is consequently very low; so low, in fact, that water cooling is not used. This tube makes possible a power saving over the older type of water-cooled power rectifiers. This 857 tube is rated, as will be noted in the description of tubes used in the transmitter at 18,000 volts and 20 amperes.

The output of the 50 kw. amplifier is coupled to the antenna unit by a two-wire transmission line. This enables the antenna to be placed at a distance from the transmitter. The transmission line, properly terminated, has an efficiency of nearly 100%; the only loss is that of the 1R loss in the conductors, which is negligible. The antenna-coupling and tuning apparatus is housed in a separate building located directly under the antenna. The transmission line is terminated in an impedance equal to its own surge impedance. This condition being strictly met, all power delivered to the transmission line is transferred to the antenna. If the transmission line should not be properly balanced and terminated, the energy which would not be transmitted to the antenna, would surge back and forth from end to end (commonly called reflections) until it was dissipated in the line itself.

**NEW VISIONETTE**

The First Practical Television for the Home

Contains all necessary parts to easily assemble and use as a Television Set.

The ICA Visionette makes the viewing of television pictures a pleasure. The pictures are seen in an adjustable mirror. This exclusive method widens the angle of view—permitting a number of people to enjoy the pictures at the same time. A specially designed and ground lens between the scanning disc and mirror magnifies the picture without loss of detail. A newly developed synchronous motor of radically different design (fully assembled, ready to operate) and 60-line scanning disc included.

**SHORT WAVE RADIO TELEVISION SET**

For use with ICA Visionette or color standard television equipment. Powerful Pustode and Vario-Ma Tubes—power supply—built-in permanent coil. Tuner in short-wave range stations or television transmitting stations—just throw a simple switch to change from one to the other. Wave lengths 80—200 meters. Single control—full vision system. Supplied complete with blueprints and detailed information for quick and easy assembly.

Follow the Direct Road to Success

Do you want a better position and a better pay envelope? Learn mathematics! Not a day passes in which you do not have to use mathematics in your work. A thorough knowledge of it makes clear so many things which are puzzling today.

You can now have a mathematics education without having to go back to school or taking an expensive correspondence course.

**At Last! Mathematics, Self-Taught, This Simple, Easy Way!**

Now you can learn this new method which has been worked out by an expert for those who do not wish to give up their time and money required by other methods of mathematical study. A very simple and extremely interesting group of books has been prepared for you by a man who has devoted his life to teaching practical mathematics from the fundamentals of this important subject.

**MATHMATICS FOR SELF-STUDY**

By J. E. Thompson, B.S. in E.E., Ph.D., Grad. of Mathematics, Pratt Institute, Brooklyn

These books start right from the begining with a review of arithmetic that gives you all special short cuts and tells you how to save hours of your time. Then they go right into higher mathematics and show you how simple it is when an expert teaches it for you. No time at all. You will be surprised with ease the most difficult question on this subject.

An Expert's Simplified Methods

Mr. Thompson, the author of these books, has had many years' experience in mathematical teaching. He presents the fundamentals of mathematics in the simplest and clearest spirit of subject. He does not expect you to know the set of items of information that you need in your daily work.
